Modeling of oscillatory growth in autotrophic denitrification for removing nitrogen from wastewater. A mathematical model was established to describe the kinetics of autotrophic denitrification in continuous-flow stirred-tank reactors (CSTRs). The whole autotrophic denitrification system was modeled as one two-compartment M-N mass-balance model. The modeling results of autotrophic denitrification by hybrid growth in CSTRs are evaluated, showing that both the ability to tolerate low concentrations of nitrate and the tolerance to high nitrate concentrations were better than previous models.
