The Magic Wand allows you to pick out just the right areas of an image by painting pixels that match the colors of the selected background. The Pen Tool allows you to draw shapes in images. You can change the shape of your lines, curves, and circles, as well as edit the color and size. The Eraser tool allows you to remove pixels and lighten or darken areas of an image. The Spot Healing Brush goes over specific spots in images to remove noise and improve image quality. The Liquify tool allows you to stretch and warp parts of an image. The Lens Blur filter applies a special blur effect to an image. The Gradient tool allows you to fill areas in images with colors of your choice. The Gradient Map tool allows you to select colors and patterns for all the pixels in an image. In many effects, you'll want to resize the image—this includes resizing within Photoshop, resizing a JPEG (it will make it as small as possible), using Image Ready (it will make it as big as possible). You'll also want to resize the image so that it fits your Web page, or so that it will fill the full width of the screen. When you resize an image, you're resizing the pixels in an image. When you edit those pixels, you are editing the photo. If you're using a large file to create a web page, you may have to optimize it. We'll touch on this in the "Optimizing Your Image" section below, but you may already be familiar with the techniques of optimizing Photoshop files: Resize images to a maximum of 1000 pixels wide and 1000 pixels tall (or 2000 pixels or more). You can also resize images in web browsers so that they shrink as needed. Save your work in Photoshop as a JPEG (or TIFF) file. If you save it as a JPEG, you'll be able to print it and save it in other applications (like PowerPoint) to make it easy to share or embed the image in your Web site. Add a Copyright and License to an image. These are the same as the copyright and license you add to your Web site when sharing your images. If you don't, Web browsers might display a warning message or block the image from displaying. Determine if your image is a Graphics Interchange Format (GIF) file. If not, you

Q: Cookie not set from JSESSIONID cookie My page uses a JSESSIONID cookie to authenticate a user. When the user logs in, I set the cookie accordingly like this in the login Action request.getCookie("JSESSIONID") When the user does something in a form, it goes through the same login Action but it makes the user wait until I reload the page before getting redirected. So the form action sets a global variable which I check in the login Action. If the variable is true, I redirect the user without waiting for the JSESSIONID cookie. It works as expected when the user goes through the form, but if the user goes back to the login page, I am not redirected because the cookie is not set yet. How can I make it so the cookie is set before the page is redirected? A: You could try calling: HttpSession session = request.getSession(true); It starts a new session if no one is started yet. A novel human nuclear receptor coactivator required for nuclear receptor action. Receptors of the nuclear receptor superfamily are transcription factors that mediate a variety of cellular processes. As transcriptional coactivators, their transcriptional activity is severely compromised when they lack a proper nuclear receptor coactivator, a protein that binds to the receptor and enhances transcription. Here we report identification of a novel human nuclear receptor coactivator (named PGC-1alpha), which is expressed preferentially in metabolically active tissues. This protein contains two domains with motifs that are highly conserved in yeast and other eukaryotes. One of the motifs is a signature of the ligand-binding domain of the nuclear receptor superfamily, the nuclear receptor box, and the other is the carboxyl-terminal region of SRC/AML1, a well-known coactivator. Both motifs and the high degree of conservation in other eukaryotes indicate that PGC-1alpha plays important roles in basic cellular processes. Semiconductor devices have become progressively more complex, driven at least in part by the requirements of decreasing size and increasing performance. One approach to semiconductor devices having finer features and higher performance is to use a metal gate electrode in a replacement metal gate (RMG) process. The RMG process reduces the number of fabrication steps required to form the gate electrode. While the conventional RMG process has
