Q: Why the install fails in Dockerfile when I use container_name: "arif-nginx" inside same Dockerfile? I'm using the same Dockerfile with the same args: ARG DOCKER_REGISTRY ARG TAG FROM debian:stretch RUN apt-get -qqy update && apt-get -qqy install nginx Dockerfile looks like this: FROM debian:stretch ARG DOCKER_REGISTRY ARG TAG RUN apt-get -qqy update && apt-get -qqy install nginx COPY test.png /var/www/html/test.png If I do docker build -t teste. the docker file is sucessfully downloaded and build. However, I want to have the image with same name "arif-nginx", so I changed to Dockerfile as this: ARG DOCKER_REGISTRY ARG TAG FROM debian:stretch ARG container_name RUN apt-get -qqy update && apt-get -qqy install nginx COPY test.png /var/www/html/test.png Dockerfile as now: FROM debian:stretch ARG DOCKER_REGISTRY ARG TAG ARG container_name RUN apt-get -qqy update && apt-get -qqy install nginx COPY test.png /var/www/html/test.png and if I do docker build -t teste. it prints a bad instruction: The command '/bin/sh -c apt-get -qqy update && apt-get -qqy install nginx' returned a non-zero code: 100 The parameters for run are empty, because I'm not having tag. So, the question is why docker doesn't find an image with the name teste? if you look into /var/lib/docker/images/br2000j/e7ca0df4f0b288d04f60c432618e828c101e16aac4f565e0767aa1871c8dca4 you'll see there is no tag. What's New In?

Protein kinases and their substrates. Protein kinases are enzymes that transfer a phosphate group from ATP to specific amino acid residues on target proteins. The targets of the protein kinases are divided into two groups: 1) peptide and protein substrates that contain the target amino acid residue that is phosphorylated, and 2) regulatory substrates that include both the effector molecules, such as the polyphosphate polymer, and the substrates for protein kinases, such as glycolytic enzymes. Protein kinases share a conserved amino acid sequence domain, which includes the ATP-binding site and the catalytic region, and thus, protein kinases form one family of the 2-fold symmetrical protein serine/threonine kinases. Two sub-groups within the protein kinase family can be distinguished by their substrates, including the specific amino acid sequences for phosphorylation, which are involved in signal transduction. Thus, the sub-group with peptide substrates, which includes casein kinase 1, 2, and epsilon, has a consensus sequence in their substrates for serine or threonine at the -1 position. In contrast, the sub-group with protein kinase substrates is more diverse. The specificity of these sub-groups is to different amino acid residues in the target sequence of the substrate protein. The protein kinases are composed of two catalytic sub-domains (N-lobe and C-lobe). The C-lobe has the ability to recognize its amino acid sequences, which are similar to the substrate, while the N-lobe is responsible for substrate binding. The protein kinase C and the calcium calmodulin kinase require a calcium ion for their activity. The activity of these calcium-dependent protein kinases is regulated by calmodulin. Peptidyl-prolyl isomerases are enzymes that catalyze conformational changes in their target proteins, including activation of heat shock proteins. Peptidyl-prolyl isomerases include two types, the cyclophilin and FKBP types. Cyclophilin is an immunosuppressive drug, and FKBP is an immunophilin. Although the crystal structures of cyclophilin and FKBP have been determined, little is known about the substrate binding domain of these proteins. There are three forms of protein kinase C (alpha, beta,

gamma). The beta- and gamma-forms have
