unlocked-partition-7.9.pdf Detection of hydroperoxide-sensitive Cys residues in porcine heart lactate dehydrogenase by trifluoperazine and other agents. The thiol-specific reagent N-ethylmaleimide (NEM) caused irreversible inactivation of lactate dehydrogenase (LDH), which was completely protected by the action of dithiothreitol. The pattern of protection against NEM inhibition was the same as previously reported for lactate dehydrogenase in horse muscle (Mackenroth, J. (1984) *Biochim. Biophys. Acta* 770, 17-22). Exogenous GSH was required to fully protect against NEM inactivation, but NEM only partially protected against hydrogen peroxide inactivation. The three known thiol redox-reactive reagents, mercuric chloride, trifluoperazine, and cyanate, were able to protect against the irreversible inhibition of porcine heart LDH by H<sub>2</sub>O<sub>2</sub>. Additionally, protection against H<sub>2</sub>O<sub>2</sub> was shown to occur through modification of a Cys residue. Methylene blue was also capable of protecting the enzyme against H<sub>2</sub>O<sub>2</sub> inactivation. The results of this study are consistent with the modification of the essential Cys-118 residue of LDH by oxidation to sulfinic and/or sulfonic acids. Intracoronary streptokinase in acute myocardial infarction: how much are the data encouraging and where is the black box? The overall results of the thromboly
