Thus, safe and efficient adsorbents for halogen compounds, such as methyl bromide and bromomethane, have been searched for. Known adsorbents include a zeolite containing Ca, which is expensive and less active. Ammonium ion-exchanged zeolite is used for removing methyl bromide. The activity of this zeolite, however, is low. On the other hand, known adsorbents for bromine include a zeolite containing K, which is expensive and is also problematic in that the K cations in the zeolite are released into the atmosphere as water during thermal decomposition, the adsorption temperature must be as high as 250.degree. C. to obtain a sufficient capacity, and the adsorption reactivity is too low to avoid undesirable, severe expansion of the cation. A co-precipitate of zeolite containing Zn and Mg is known as a more active adsorbent. The adsorption capacity is, however, low, and, it is, therefore, difficult to completely remove bromine even if activated carbon is added to it in a large amount. Zeolite containing Al is very cheap, but it is also low in reactivity, though the bromine adsorption capacity is high
